

# Bridge Lemma proof

## Lemma

If  $e = uv$  is a bridge in a connected graph  $G$ , then  $G-e$  has exactly 2 connected components, one containing  $u$  and the other containing  $v$ .

## Proof(by contradiction)

1) In  $G-e$ , suppose  $u$  and  $v$  are in the same connected component  $H$ , since  $H$  is connected, there must exist some path  $p$  from  $u$  to  $v$ . If  $p$  exists in  $G-e$ , it must exist in  $G$ . With  $e$  and  $p$  both connecting  $u$  and  $v$  in  $G$ , there exists a cycle containing  $e$  between  $u$  and  $v$ . It contradicts the given condition that  $e$  is a bridge in  $G$ , so  $u$  and  $v$  must be in different components.

2) we know  $G-e$  must contain at least 2 connected components. When connecting  $u$  and  $v$  by  $e$ ,  $e$ , as an edge, can at most only join 2 vertices, which means  $e$  can only connect the 2 disconnected components that contain  $u$  and  $v$ . If there are more than 2 disconnected components in  $G-e$ , the components without  $u$  and  $v$  will stay isolated. We know joining  $u$  and  $v$  by  $e$  in  $G-e$  will give us  $G$ . In the above situation with more than 2 disconnected components in  $G-e$ , only components containing  $u$  and  $v$  will be connected by adding  $e$  while other components stay isolated, so  $G$  is disconnected, while the given condition says  $G$  is connected, so it contradicts. So only can there be exactly 2 disconnected components, one containing  $u$  and the other containing  $v$ , could satisfy when joining  $u$  and  $v$  by  $e$  will give a connected graph.

Combining 1) and 2), lemma proved.
